PROFESSIONAL SUMMARY

I'm a Flutter developer with around 3 years of experience building Android and iOS apps, including apps live in production on the App Store and Google Play. My core stack is Flutter/Dart with Bloc/Cubit, Dio for API integration, and Arabic/English (RTL) localization built on shared themes and reusable components I carry between projects.

My work focuses on HR/attendance, logistics/delivery, and enterprise ERP apps, including full ownership of a multi-module ERP system built end-to-end. I'm most comfortable with the harder features: biometric face and liveness verification, barcode/QR scanning, and real-time notifications. Since June 2026 I've been working beyond the mobile side as well — backend development with C#/ASP.NET Core (ABP Framework), building API endpoints for a freight platform — which has made me sharper about how the mobile and server sides fit together. I care most about the less glamorous side of shipping: solid validation, error handling, and the production debugging that keeps releases stable.

WORK HISTORY

Full-Stack Mobile Developer

Advanced Achievement Company for Information Technology Ltd. | 06/2026 – Current | Baghdad, Iraq

- In addition to my mobile role, started backend development with C#/ASP.NET Core (ABP Framework) in June 2026.
- Contributed to the Noon Express backend (.NET / ABP), building the freight gateway endpoints — merchant registration, shipment booking, and lookup APIs.

Mobile Application Developer

Advanced Achievement Company for Information Technology Ltd. | 10/2025 – Current | Baghdad, Iraq

- Develop and maintain Flutter apps for a large, multi-module enterprise ERP suite (Inventory, Finance, HR, Point of Sale, and more) used by Arabic-, English- and Kurdish-speaking staff, with full RTL support.
- Built the biometric attendance flow: on-device face detection and liveness checks (randomized head-turn / smile challenges), plus GPS capture with mock-location rejection, to help prevent spoofed photos and off-site check-ins (face matching handled server-side).
- Took over Noon Express, a live last-mile delivery app, after its initial release — implementing new features, refactoring the codebase, and maintaining releases.
- Structure features around Bloc/Cubit and clean architecture (use-cases, repositories) to keep the codebase scalable and maintainable.
- Integrate REST APIs with Dio, implementing interceptors, JWT token refresh, and standardized error mapping shared app-wide.
- Build responsive UIs on a shared light/dark theming system and a reusable component library to speed up delivery of new screens.

- Partner with backend and QA to ship stable releases, and support production by analyzing logs, reproducing issues, and delivering fixes.

EDUCATION

Bachelor of Informatics Engineering

Al Sham Private University | 02/2019 – 01/2024 | Damascus, Syria

- Software development, programming fundamentals, object-oriented programming, database design, web development, mobile application development, computer networks, operating systems, software engineering, systems analysis and design, and problem-solving skills.
- Field of study: Informatics Engineering | Website: aspu.edu.sy

LANGUAGES

Mother tongue(s): Arabic
Other language(s): English

PROJECTS

Noon Express Mobile App (Flutter — Full-stack)

11/2025 – Current

Noon Express — a live last-mile delivery app, published on both the App Store and Google Play. I joined after the initial release and continued its development: implementing new features, refactoring the codebase, and publishing updates to the App Store and Google Play. The app serves merchants, delivery drivers, and back-office staff from a single Flutter codebase, covering order management, batch QR/barcode scanning (driver pick-up, delivery sessions, and returns receiving), order returns and exchanges, merchant and driver settlements with Excel export, a map-based address picker, deep-linked order screens, and real-time notifications (SignalR + Firebase Cloud Messaging), with full Arabic/English (RTL) localization. Built with Bloc/Cubit state management and Dio for REST APIs. On the backend (.NET / ABP), I built the gateway endpoints that connect the platform to the freight booking system — merchant registration, shipment booking, and lookup APIs.

ENKI ERP — Cross-Platform Mobile Suite (Flutter)

11/2025 – Current

Cross-platform Flutter client for ENKI ERP, a modular enterprise system, published on Google Play and the App Store. Built and shipped 10 modules end-to-end — HR/Attendance, Finance, Inventory, Sales, Purchasing, Manufacturing, Point of Sale, Archive (DMS), workflow-based Form Service, and Freight — on a shared, layered architecture (Bloc/Cubit, use-cases, repositories, Dio) with permission-based access, barcode/QR scanning (inventory and POS), PDF invoice and receipt printing, and real-time notifications (FCM + SignalR). The Attendance module includes on-device face detection and liveness detection (randomized head-turn / smile challenges) and GPS capture with mock-location rejection — with face matching handled server-side — to help prevent spoofed photos and off-site check-ins. It also covers shift scheduling and swaps and leave management, with Arabic, English, and Kurdish support (full RTL).

Freight & Shipping Mobile App (Flutter)

07/2026 – Current

Cross-platform mobile app for a freight logistics platform, published on both the App Store and Google Play. Covers the shipment lifecycle: registration and token-based login (OpenIddict), shipment booking with document and image upload, a shipment dashboard, and status tracking through a live timeline, with real-time notifications over SignalR and Firebase Cloud Messaging (deep-linked to the relevant order). Also includes cargo-inspection requests, complaints, customer surveys with star ratings, and a directory of the company's network locations with a map location picker. Integrates with a .NET (ABP)

backend over REST with multi-tenant request handling and multi-account switching. Built with Bloc/Cubit and a clean layered architecture (use-cases, repositories, get_it), Dio, and Hive caching; bilingual (Arabic-first / English) with RTL and light/dark theming.

Warehouse Management Mobile App (Flutter)

05/2026 – Current · In development

Building a cross-platform mobile app in Flutter/Dart (currently in development, not yet released) that lets third-party logistics teams run warehouse operations from their phones, connecting to an ERP backend over a REST API. It covers the full inbound/outbound flow — stock-in and stock-out order creation, editing, and tracking through the posting lifecycle, with batch, expiry, and warehouse/bin selection per line — plus item, unit-of-measure, and organization lookups feeding order entry, a searchable inventory-balance report with item detail, and authentication (email and Google sign-in). The codebase follows clean architecture with a Cubit/Bloc state layer and dependency injection, keeping features as self-contained vertical slices, with unit tests covering the order-edit logic. The app is Arabic-first with full right-to-left support and English localization, and ships a custom design system for consistent theming across screens.

Store Management System — Flutter + .NET (Full-stack)

06/2026 – Current · In development

Cross-platform store management app with its own backend, designed and built solo end to end. The Flutter app lets store owners manage products, categories, and inventory — including automatic size/colour variant generation and bulk creation, image upload, a stock dashboard with low-stock and out-of-stock alerts, soft-delete with a restore screen, and the full order lifecycle — on a feature-based clean architecture (Cubit, repositories/use-cases, get_it) with Dio, Hive local storage, and Arabic/English/Bengali localization with RTL. The backend is C#/ASP.NET Core (.NET 10) on the ABP Framework with a domain-driven layered architecture: auditable stock-movement history, an order draft–confirm–cancel lifecycle that deducts stock on confirmation and restores it on cancellation, cash/card/bank-transfer payments with partial-payment tracking, and permission-based access on OpenIddict/JWT authentication — backed by EF Core.

SKILLS

Languages: Dart

Mobile: Flutter, Android, iOS, Cross-platform development, Responsive UI (flutter_screenutil)

State Management & Architecture: Bloc/Cubit, Clean/layered architecture, Use-cases & repositories, Dependency injection (get_it), GetX

API & Data: REST API integration, Dio, JSON serialization, Pagination, Local storage (Hive), Caching, JWT auth & token refresh

Device & Platform Features: Camera & image capture, Google ML Kit (face detection), Biometric verification & liveness detection, Geolocation, maps & real-time tracking, Local/push notifications, Permissions handling, Platform channels (native integration)

UI/UX: Design systems & theming, Reusable component libraries, Localization & RTL (Arabic/English/Kurdish), SVG & animations, Loading/skeleton states

Release & Publishing: App Store & Google Play publishing, TestFlight, release management

Backend (.NET): ASP.NET Core (ABP Framework), EF Core, SignalR, JWT, OpenIddict
